Methods and formulas used to calculate the GRACE Risk Scores for patients presenting to hospital with an acute coronary syndrome:

Coordinating Center for the Global Registry of Acute Coronary Events (grace@umassmed.edu)
Center for Outcomes Research, University of Massachusetts Medical School

Fred Anderson, PhD, Director (fred.anderson@umassmed.edu)
Gordon FitzGerald, PhD, Senior Biostatistician (Gordon.fitzgerald@umassmed.edu)

IN-HOSPITAL MODELS

1. 8 Granger reduced model estimates for hospital death
   Arch Int Med, Oct 2003
   (Can be used to estimate the probability of hospital death.)

2. Translation of 8 estimates into Granger risk score (nomogram)

3. How Granger risk score relates to probability of hospital death
   (Note- probability computed directly from model estimates in #1 should be slightly more accurate, as a single score cannot completely replace 8 distinct factors.)

4. Risk score for in-hospital death or MI (nomogram)

POST DISCHARGE MODELS

5. 9 Eagle reduced model estimates for death in 6 months after discharge
   JAMA, June 2004
   (Can be used to estimate the probability of 6-month death.)

6. Translation of 9 estimates into Eagle risk score (nomogram)

7. Risk score for death or MI in 6 months after discharge (nomogram)

ADMISSION TO 6 MONTHS MODELS

8. Risk score for Fox prediction of death from admission to 6 months later (nomogram)
   BMJ, Oct 2006

9. Risk score for Fox prediction of death or MI from admission to 6 months later (nomogram)
Granger Model for In-hospital Death

1. Model estimates from multiple logistic regression model

* enter a value of 1 if factor is present, 0 otherwise.

To obtain estimated risk of death from above estimates

Compute $XB$, where $X$=individual patient's value for each factor (eg, age=57, pulse=70…), and $B$=estimates above, including the intercept.

$XB$ is then the summed product of the patient characteristics times the estimates, with the intercept added for every patient.

For example, if a patient is age 57, pulse 70, SBP 110, creatinine 1.2, Killip class III, had cardiac arrest and ST deviation but not initial positive enzymes, $XB$ is:

The probability of in-hospital death is then

$P = \frac{\exp(XB)}{1 + \exp(XB)} = .21693$,

where $\exp$ is 2.71828…, and ** means raised to that power ($XB$ power).

The SAS macro below illustrates this computation for a given patient

```sas
%macro xb(val1,val2,val3,val4,val5,val6,val7,val8);
data x;
  age=&val1;
pulse=&val2;
sbp=&val3;
creat=&val4;
killip=&val5;
carrst=&val6;
posinit=&val7;
stchange=&val8;
xb= -7.7035 + (0.0531*age) + (0.0087*pulse) - (0.0168*sbp) + (0.1823*creat) + (0.6931*killip) + (1.4586*carrst) + (0.4700*posinit) + (0.8755*stchange);
p=(exp(xb))/(1 + exp(xb));
run;
%mend xb;
%xb(val1=57,val2=70,val3=110,val4=1.2,val5=3,val6=1,val7=0,val8=1);
```
2. Nomogram translating Eight Granger Model estimates for in-hospital death into integer GRACE Risk Scores (see pg. 2351 of Granger article)

* enter a value of 1 if factor is present, 0 otherwise.

To obtain estimated risk of death from above estimates
Compute XB, where X=individual patient's value for each factor (eg, age=57, pulse=70...), and
B=estimates above, including the intercept.
XB is then the summed product of the patient characteristics times the estimates, with the intercept added
for every patient.

For example, if a patient is age 57, pulse 70, SBP 110, creatinine 1.2, no positive initial enzymes, had ST
depression, no past MI, past CHF, had in-hospital PCI, XB is:

\[
XB = 57 \times 0.05713 + 70 \times 0.00891 - 110 \times 0.0063 + 1.2 \times 0.15807 + 0 \times 0.47321 + 1 \times 0.36053 + 0 \times 0.39271 + 1 \times 0.76678 - 1 \times 0.44618 = 4.05792.
\]

The probability of in-hospital death is then
\[
P = \text{baseline survival} \times (\exp \times XB) = 0.0285,
\]
where base survival is .9995, exp is 2.71828..., and ** means raised to that power (so .9995 raised to the
(2.71828 raised to the XB power)).

The SAS macro below illustrates this computation for a given patient

```sas
%macro prob(val1, val2, val3, val4, val5, val6, val7, val8, val9, val10);
data x;
age=&val1; pulse=&val2; bpsys=&val3; creat=&val4; posinit=&val5; stdepr=&val6; mhmi=&val7; mhchf=&val8; nopci=&val9; basesurv=&val10;
xbeta = (age*0.05713) + (pulse*0.00891) - (bpsys*0.0063) + (creat*0.15807) + (posinit*0.47321) + (stdepr*0.36053) + (mhmi*0.39271) + (mhchf*0.76678) - (pci*0.44618);
exbeta=exp(xbeta);
cumsurv=basesurv**exbeta;
p=1-cumsurv;
run;
proc print data=x; run;
%mend
```

```sas
%prob(val1=57, val2=70, val3=110, val4=1.2, val5=0, val6=1, val7=0, val8=1, val9=1, val10=.9995);
```
6. Nomogram translating nine Eagle Model estimates for death within the 6 months after discharge into GRACE Risk Score integers
(see pg. 2731 of 2004 JAMA article)

SAS code for obtaining risk score as in article

* 1. Age in years;
   if 0 <= age < 35 then age_sc = 0;
   else if 35 <= age < 45 then age_sc = 0 + (age-35)*((18-0)/10);

How risk score for 6-month death/MI relates to probability of 6-month death/MI (from Palm Pilot software)

Please NOTE:
Because the death/MI score ignores 5 factors in the death model, it's possible the death probability > death/MI prob based on solely on score. In such cases, the death/MI prob is made > death prob, since it's illogical to have the combined death/MI prob. be < death prob.
